

PARAMETER CHOICE STRATEGIES FOR MULTIPENALTY REGULARIZATION*

MASSIMO FORNASIER[†], VALERIYA NAUMOVA[‡], AND SERGEI V. PEREVERZEV[§]

Abstract. The widespread applicability of the multipenalty regularization is limited by the fact that theoretically optimal rate of reconstruction for a given problem can be realized by a one-parameter counterpart, provided that relevant information on the problem is available and taken into account in the regularization. In this paper, we explore the situation where no such information is given, but still accuracy of optimal order can be guaranteed by employing multipenalty regularization. Our focus is on the analysis and the justification of an a posteriori parameter choice rule for such a regularization scheme. First we present a modified version of the discrepancy principle within the multipenalty regularization framework. As a consequence we provide a theoretical justification to the multipenalty regularization scheme equipped with the a posteriori parameter choice rule. We then establish a fast numerical realization of the proposed discrepancy principle based on a model function approximation. Finally, we provide extensive numerical results which confirm and support the theoretical estimates and illustrate the robustness and the superiority of the proposed scheme compared to the “classical” regularization methods.

Key words. multipenalty regularization, discrepancy principle, model function, order-optimal reconstruction, compensatory properties

1. Introduction. In recent years there has been a fast growing interest in studying multipenalty regularization for solving inverse and ill-posed problems. In several inspiring applications such as image reconstruction, option pricing [7, 19], reconstruction of the Earth gravity potential [30, 2], multipenalty regularization schemes have been successfully applied. Moreover, relevant theoretical results appeared in a few papers (see, for instance, [3, 4, 5, 9, 11, 17, 26]). However, apart from recent promising results the widespread applicability of the multipenalty regularization has remained questionable due to the fact that the theoretically optimal rate of reconstruction for a given problem can be realized by a one-parameter counterpart. One-parameter regularization is well developed and proves to be particularly simple and effective, though only in the case when relevant information on a solution is provided. Precisely, in this case, the theory of inverse and ill-posed problems provides us with a concrete recipe on how to measure the accuracy of the reconstruction.

It is well known that the reconstruction accuracy depends on a noise model and on the smoothness of the solution. On the one hand, the noise model is provided together

with the given data and cannot be changed. On the other hand, the smoothness can be measured in various spaces (see, for instance, [20]), and depending on this, different bounds on the best possible approximation can be derived. Once this space is fixed, the general regularization theory provides us with the best possible error bound that can be achieved if the regularization is performed in the chosen space. Moreover, the theory promises us that this bound can be achieved in the framework of the one-parameter regularization [8, 18].

However, one principal problem is left untouched: Who is going to tell us in which space we need to measure the smoothness of the unknown solution? Apparently, this principal question started to be discussed only recently and have not yet been systematically explored in regularization theory.

Differently from the “classical” works on regularization theory, we continue to investigate in this paper multipenalty regularization, where one is given the freedom of performing the regularization in several spaces simultaneously with the goal of possibly achieving a better accuracy than given by an a priori fixed one-parameter counterpart. Definitely one of the leading ingredients for the optimal performance of multipenalty regularization is an appropriate (a posteriori) choice of the multiple regularization parameters. This issue has been essentially studied in the framework of multiparameter regularization in the papers [3, 11, 17, 12]. However, as will be seen later, the theory developed in [11, 17] is not sufficient for multipenalty regularization and needs to be extended. The conceptually closest work [26] considers a heuristic parameter choice rule strategy, though it does not provide any theoretical justification. In this paper we will combine theoretical and heuristic concepts of the parameter choice strategies to justify the optimality of multipenalty regularization equipped with an a posteriori parameter choice rule.

The rest of the paper is organized as follows: section 2 is devoted to studying a multiparameter discrepancy principle, the so-called *discrepancy domain principle*, as a parameter choice rule for multipenalty regularization. We show that there exist many combinations of the regularization parameters satisfying the discrepancy principle which correspond to a reconstruction accuracy of the optimal order. While the estimation of the discrepancy requires the computation of a solution relative to each pair of parameters, which can be a demanding task, in section 3 we replace the exact discrepancy by a locally approximating surrogate function of the parameters. We show that the proposed model function approximation of the discrepancy domain leads to an efficient iterative algorithm for choosing the regularization parameters. The paper is concluded by extensive numerical experiments involving toy and simulated problems which clearly demonstrate that the proposed scheme allows us to achieve better results than the corresponding one-parameter competitor. Additionally, we demonstrate how the model function approximations can be profitably used to find a domain of the regularization parameters, which leads to the optimal order of the reconstruction accuracy.

2. Preliminaries. As mentioned previously, we are in particular interested in the solution of a linear ill-posed problem

$$(2.1) \quad Ax = y,$$

where $A : X \rightarrow Y$ is a bounded linear operator between Hilbert spaces X and Y with a nonclosed range $\mathcal{R}(A)$. We denote the inner product and the corresponding norm on the Hilbert spaces by $\langle \cdot, \cdot \rangle$ and $\|\cdot\|$, respectively. In what follows, we assume that the operator A is injective and y belongs to $\mathcal{R}(A)$ such that there exists a unique

solution $x^\dagger \in X$ of (2.1). In general, the observed data are additionally corrupted by noise ξ ,

$$(2.2) \quad y_\delta = Ax^\dagger + \xi,$$

where $\xi \in Y$, $\|\xi\| \leq \delta$, $\delta \in (0, 1)$. Due to nonclosedness of $\mathcal{R}(A)$, the solution x^\dagger does not depend continuously on data and can be reconstructed in a stable way from y_δ only by means of a regularization method [8].

A well-known technique to stabilize an ill-posed problem is by Tikhonov–Phillips (TP) regularization, i.e., by minimizing the functional

$$(2.3) \quad TP(\alpha; x) = \|Ax - y_\delta\|_Y^2 + \alpha\|x\|_X^2.$$

The minimization has a unique solution

$$(2.4) \quad x_\alpha^\delta = x_\alpha^\delta(y_\delta) = (\alpha\mathbb{I} + A^*A)^{-1}A^*y_\delta$$

with $\alpha > 0$ being the regularization parameter and \mathbb{I} is the identity operator.

Let us briefly recall that the accuracy of the reconstruction depends both on the noise model and on the smoothness of the solution. For regularization methods such as (2.3) of the operator equation (2.1) in Hilbert spaces, the smoothness of x^\dagger is usually expressed in the form of the inclusion

$$(2.5) \quad x^\dagger \in A_\varphi(R) := \{x \in X : x = \varphi(A^*A)g, \|g\|_X \leq R\},$$

where $\varphi : [0, \|A\|^2] \rightarrow [0, 1]$, $\varphi(0) = 0$, is called an index function which is assumed to be continuous, increasing, and such that $\frac{t}{\varphi(t)}$ is nondecreasing. Note that the condition of the type (2.5) is usually called the *source condition* (see, [21, 20], for instance). Then the order of the best possible accuracy, which can be guaranteed within the framework of the given noise model for x_α^δ , is given as

$$\inf_{\alpha} \sup_{x^\dagger \in A_\varphi(R)} \sup_{y_\delta} \|x^\dagger - x_\alpha^\delta(y_\delta)\|_X = O(\varphi(\theta_\varphi^{-1}(\delta))),$$

where $\theta_\varphi(t) = \varphi(t)\sqrt{t}$ and $\varphi^2((\theta_\varphi^2)^{-1}(t))$ is assumed to be concave. This order is attainable at $\alpha = \theta_\varphi^{-1}(\delta)$. Since $\varphi(t) = ct$ is the best index function for which $\frac{t}{\varphi(t)}$ is nondecreasing, the best guaranteed error for TP regularization is known to be $O(\delta^{2/3})$, regardless of the smoothness of the solution x^\dagger .

On the other hand, this order can be potentially improved if one employs the original idea of Tikhonov [27] and changes the form of the penalty term in (2.3), namely, instead of the identity operator \mathbb{I} within the penalty term, an unbounded self-adjoint strictly positive operator B on the Hilbert space X is considered. In this case, the regularized solution $x_{\beta,B}^\delta$ is defined as the minimizer of the functional

$$(2.6) \quad T(\beta; x) = \|Ax - y_\delta\|_Y^2 + \beta\|Bx\|_X^2$$

over the domain $\mathcal{D}(B)$ of the operator B . In the classical work of Tikhonov [27], the operator B is given as a square root of the self-adjoint second order differential operator.

However, the superiority of the latter regularization scheme over (2.3) has been theoretically justified only under the assumption that the operators A and B are related by the so-called *link condition* for which

$$(2.7) \quad \|B^{-s}x\| \leq \|Ax\| \leq b\|B^{-s}x\| \quad \text{for all } x \in X,$$

where $s > 0$ and $b \geq 1$ are some constants. Then Natterer [25] has shown that the regularized solutions $x_{\beta,B}^\delta$ converge towards the exact solution with the rate $O(\delta^{\frac{p}{p+s}})$ in the norm of X , if the regularization parameter β is chosen properly and if the exact solution x^\dagger satisfies an analog of the source condition formulated in terms of the operator B as follows:

$$(2.8) \quad x^\dagger \in \mathcal{D}(B^p) = \{x : x = B^{-p}g, \|g\|_X \leq R\}, \quad p > 0.$$

It is easily seen that under assumptions (2.7), (2.8), and $p > 2s$ the best guaranteed error for Tikhonov regularization is better than the one guaranteed for TP regularization.

However, the efficiency of Tikhonov regularization is limited by a serious bottleneck. Precisely, the theoretical superiority of $x_{\beta,B}^\delta$ is justified only under the link condition (2.7), which is sometimes hardly verifiable. At the same time, when the link condition is violated Tikhonov regularization may perform poorly as will be shown in the last section.

Since in reality we do not know the smoothness of x^\dagger , it is not clear which of the source conditions should be taken into account in the regularization and which of the one-parameter regularization methods is more suitable for the problem at hand. In the spirit of DeVore [6], we require the blindness of the algorithms with respect to the conditions (of smoothness) on the solution (which is unknown!) for achieving optimal approximation.

In the recent paper [26] a new multipenalty regularization scheme as an addresser of the abovementioned problematic issue has been introduced. In this scheme one considers the multiobjective optimization of a functional of the form

$$(2.9) \quad \Phi(\alpha, \beta; u, v) := \|A(u + v) - y_\delta\|_Y^2 + \alpha\|u\|_X^2 + \beta\|Bv\|_X^2.$$

The minimizers $u_{\alpha,\beta}^\delta$ and $v_{\alpha,\beta}^\delta$ of (2.9) have the representation

$$(2.10) \quad u_{\alpha,\beta}^\delta = (\alpha\mathbb{I} + A^*A)^{-1} (A^*y_\delta - A^*Av_{\alpha,\beta}^\delta),$$

$$(2.11) \quad v_{\alpha,\beta}^\delta = \alpha (\beta B^2 + \alpha A^*A(\alpha\mathbb{I} + A^*A)^{-1})^{-1} (\alpha\mathbb{I} + A^*A)^{-1} A^*y_\delta,$$

and a reconstruction of the solution of interest $x_{\alpha,\beta}^\delta$ is calculated then as the sum of these minimizers. For the sake of completeness, we recall the theorem from [26], which shows the compensatory properties of multipenalty regularization, in the sense that it performs similarly to the best of the single-parameter regularizations with the corresponding penalizing operator, either \mathbb{I} or B .

THEOREM 2.1.

- (1) Assume that the link condition (2.7) is satisfied. Then for $\alpha > 1$ there is $\beta = \beta(\alpha, \delta, y_\delta)$ such that $x_{\alpha,\beta}^\delta = u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta$ approximates x^\dagger with the best order of accuracy guaranteed by the Tikhonov method.
- (2) Assume that the link condition (2.7) is violated. Then for $\beta > 1$ there is $\alpha = \alpha(\beta, \delta, y_\delta)$ such that $x_{\alpha,\beta}^\delta = u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta$ approximates x^\dagger with the best order of accuracy guaranteed by the TP method.

3. Discrepancy domain principle. In order to provide a practical and theoretically justified rule for the choice of optimal parameters as claimed in Theorem 2.1, we need here to extend the well-known theory of regularization for single parameter to multipenalty regularization. Recall that for the single-parameter regularization schemes, such as (2.3)–(2.4) or (2.6), for example, the discrepancy principle [23]

$$\alpha_{DP} = \max\{\alpha : \|Ax - y_\delta\| \leq c\delta\}, \quad c > 1, \quad \text{with } x = x_\alpha^\delta \text{ or } x = x_{\beta,B}^\delta,$$

is theoretically justified to be an order-optimal parameter choice rule under the conditions that in (2.5) the function φ is such that $\frac{\sqrt{t}}{\varphi(t)}$ is nondecreasing, or (2.7), (2.8) hold with $p \leq s + 2$.

Here we consider an extension of the classical discrepancy principle and look for a parameter set (α, β) satisfying the so-called discrepancy domain principle, i.e.,

$$(3.1) \quad (\alpha, \beta) \in D(\delta) = \{(\alpha, \beta) : \delta < \|A(u_{\alpha, \beta}^\delta + v_{\alpha, \beta}^\delta) - y_\delta\| \leq c\delta\}, \quad c > 1.$$

Here and below we will follow the convention that the symbol c denotes a quantity that does not depend on α, β , and δ and needs not be the same at different occurrences.

For technical reasons, in the following proofs we shall mainly consider the discrepancy domain principle to be given in terms of the equality, namely,

$$(3.2) \quad \|A(u_{\alpha, \beta}^\delta + v_{\alpha, \beta}^\delta) - y_\delta\| = c\delta, \quad c > 1,$$

whereas in the numerical experiments we follow (3.1).

3.1. Error bound under satisfied link condition. We begin with the case where the link condition is satisfied. The following theorem shows that multipenalty regularization equipped with the a posteriori parameter choice rule allows us to achieve the best order of accuracy guaranteed by Tikhonov regularization.

THEOREM 3.1. *Let the link condition (2.7) be satisfied with $s > 1$, and $x^\dagger \in \mathcal{D}(B^p)$, $p \in [1, s+2]$. Then for any $(\alpha, \beta) \in D(\delta)$ such that $\alpha > 1$, we have an order-optimal error bound*

$$(3.3) \quad \|x^\dagger - (u_{\alpha, \beta}^\delta + v_{\alpha, \beta}^\delta)\| = O(\delta^{\frac{p}{p+s}}),$$

where the coefficient implicit in the O -symbol depends only on $\|B^p x^\dagger\|$ and $\|A\|$.

Before providing the proof we need to recall the notion of a Hilbert scale $\{X_k\}$ induced by the operator B , where X_k is the completion of $\mathcal{D}(B^k)$ with respect to the Hilbert space norm $\|x\|_k = \|B^k x\|$.

Proof. The difference between the exact solution x^\dagger and its approximation given by multipenalty regularization can be bounded as

$$(3.4) \quad \|x^\dagger - (u_{\alpha, \beta}^\delta + v_{\alpha, \beta}^\delta)\| \leq \|x^\dagger - v_{\alpha, \beta}^\delta\| + \|u_{\alpha, \beta}^\delta\|.$$

Keeping in mind that $y_\delta = Ax^\dagger + \xi$ and $\alpha > 1$ we can deduce from (2.10) that

$$\begin{aligned} \|u_{\alpha, \beta}^\delta\| &\leq \|(\alpha\mathbb{I} + A^*A)^{-1}A^*A(x^\dagger - v_{\alpha, \beta}^\delta)\| + \|(\alpha\mathbb{I} + A^*A)^{-1}A^*\xi\| \\ &\leq \|x^\dagger - v_{\alpha, \beta}^\delta\| + \frac{\delta}{2\sqrt{\alpha}} \leq \|x^\dagger - v_{\alpha, \beta}^\delta\| + \frac{\delta}{2}. \end{aligned}$$

Hence, it is sufficient to estimate $\|x^\dagger - v_{\alpha, \beta}^\delta\|$. Assume that (α, β) is a set of positive parameters satisfying the discrepancy domain principle and $u_{\alpha, \beta}^\delta$, $v_{\alpha, \beta}^\delta$ are the solutions corresponding to (α, β) . Taking into account that $u_{\alpha, \beta}^\delta$, $v_{\alpha, \beta}^\delta$ are the minimizers of the functional (2.9), we have

$$\begin{aligned} \|A(u_{\alpha, \beta}^\delta + v_{\alpha, \beta}^\delta) - y_\delta\|^2 + \alpha \|u_{\alpha, \beta}^\delta\|^2 + \beta \|Bv_{\alpha, \beta}^\delta\|^2 &\leq \|Ax^\dagger - y_\delta\|^2 + \beta \|Bx^\dagger\|^2 \\ &\leq \delta^2 + \beta \|Bx^\dagger\|^2. \end{aligned}$$

Since the discrepancy domain principle is satisfied, with (3.2) as a defining condition, this inequality yields

$$c^2\delta^2 + \alpha \|u_{\alpha, \beta}^\delta\|^2 + \beta \|Bv_{\alpha, \beta}^\delta\|^2 \leq \delta^2 + \beta \|Bx^\dagger\|^2.$$

Keeping in mind that $\beta > 0$ and $c \geq 1$, we can conclude that $\|Bv_{\alpha,\beta}^\delta\| \leq \|Bx^\dagger\|$ and

$$\begin{aligned}\|Bv_{\alpha,\beta}^\delta - Bx^\dagger\|^2 &= \langle Bv_{\alpha,\beta}^\delta, Bv_{\alpha,\beta}^\delta \rangle - 2\langle Bv_{\alpha,\beta}^\delta, Bx^\dagger \rangle + \langle Bx^\dagger, Bx^\dagger \rangle \\ &\leq 2\langle Bx^\dagger, Bx^\dagger \rangle - 2\langle Bv_{\alpha,\beta}^\delta, Bx^\dagger \rangle \\ &= 2\langle Bx^\dagger - Bv_{\alpha,\beta}^\delta, Bx^\dagger \rangle = 2\langle B^2(x^\dagger - v_{\alpha,\beta}^\delta), x^\dagger \rangle \\ &= 2\langle B^{2-p}(x^\dagger - v_{\alpha,\beta}^\delta), B^p x^\dagger \rangle \leq 2R \|B^{2-p}(x^\dagger - v_{\alpha,\beta}^\delta)\|.\end{aligned}$$

In terms of the Hilbert scales the latter inequality can be rewritten as

$$\|x^\dagger - v_{\alpha,\beta}^\delta\|_1^2 \leq 2R \|x^\dagger - v_{\alpha,\beta}^\delta\|_{2-p}.$$

The rest of the proof is based on the interpolation inequality

$$(3.5) \quad \|x\|_r \leq \|x\|_{-s}^{(a-r)/(s+a)} \|x\|_a^{(s+r)/(s+a)}$$

which holds for all $r \in [-s, a]$, $a + s \neq 0$.

Taking $r = 2 - p$ and $a = 1$ we can continue as follows:

$$\|x^\dagger - v_{\alpha,\beta}^\delta\|_1^2 \leq 2R \|x^\dagger - v_{\alpha,\beta}^\delta\|_{2-p} \leq 2R \|x^\dagger - v_{\alpha,\beta}^\delta\|_1^{(2+s-p)/(s+1)} \|x^\dagger - v_{\alpha,\beta}^\delta\|_{-s}^{(p-1)/(s+1)},$$

which is the same as

$$\|x^\dagger - v_{\alpha,\beta}^\delta\|_1 \leq (2R)^{(s+1)/(s+p)} \|x^\dagger - v_{\alpha,\beta}^\delta\|_{-s}^{(p-1)/(s+p)}.$$

Observe now that from (2.10) and (3.2) it follows that for $\alpha > 1$ we have

$$\begin{aligned}c\delta &= \|A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta) - y_\delta\| = \|Av_{\alpha,\beta}^\delta - y_\delta + A(\alpha\mathbb{I} + A^*A)^{-1}(A^*y_\delta - A^*Av_{\alpha,\beta}^\delta)\| \\ (3.6) \quad &= \|(\mathbb{I} - A(\alpha\mathbb{I} + A^*A)^{-1}A^*)(Av_{\alpha,\beta}^\delta - y_\delta)\| \geq (1 + \|A\|^2)^{-1} \|Av_{\alpha,\beta}^\delta - y_\delta\|.\end{aligned}$$

Using this bound and the link condition (2.7) we get

$$\begin{aligned}\|x^\dagger - v_{\alpha,\beta}^\delta\|_{-s} &\leq \|Ax^\dagger - Av_{\alpha,\beta}^\delta\| \leq (\|y - y_\delta\| + \|y_\delta - Av_{\alpha,\beta}^\delta\|) \\ &\leq \delta(1 + c(1 + \|A\|^2)).\end{aligned}$$

Then we obtain

$$\|x^\dagger - v_{\alpha,\beta}^\delta\|_1 \leq (2R)^{(s+1)/(s+p)} (1 + c(1 + \|A\|^2))^{(p-1)/(s+p)} \delta^{(p-1)/(s+p)}.$$

Using again interpolation inequality (3.5) with $r = 0$ and $a = 1$, we finally receive the statement of the theorem

$$\begin{aligned}\|x^\dagger - v_{\alpha,\beta}^\delta\|_0 &\leq \|x^\dagger - v_{\alpha,\beta}^\delta\|_1^{s/(s+1)} \|x^\dagger - v_{\alpha,\beta}^\delta\|_{-s}^{1/(s+1)} \\ (3.7) \quad &\leq (2R)^{s/(s+p)} (1 + c(1 + \|A\|^2))^{p/(s+p)} \delta^{p/(s+p)}.\end{aligned}$$

The fact that for $x^\dagger \in \mathcal{D}(B^p)$ the order of accuracy $O(\delta^{\frac{p}{s+p}})$ cannot be in general improved follows, for example, from [24]. \square

Remark 3.2. Actually, one can choose $\alpha > \alpha^0 > 0$ changing the lower bound in (3.6) and eventually the constant in (3.7). However, the larger α^0 is the better and just to fix a bound we choose $\alpha^0 \equiv 1$.

3.2. Error bound under violated link condition. Now, assuming that the link condition is violated, we will show that the best order of accuracy guaranteed by TP regularization is achieved by multipenalty regularization equipped with the a posteriori parameter choice rule.

THEOREM 3.3. *Let (2.5) be satisfied. Then, for any $(\alpha, \beta) \in D(\delta)$ such that $\beta > \|B^{-2}\| \max\{\|A\|, \|A\|^2\}$, we have an order-optimal error bound*

$$(3.8) \quad \|x^\dagger - (u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta)\| = O(\varphi(\theta_\varphi^{-1}(\delta))),$$

where $\frac{\sqrt{t}}{\varphi(t)}$ is a nondecreasing function and $\theta_\varphi(t) = \varphi(t)\sqrt{t}$.

Proof. From (2.10), (2.11) we get

$$\beta B^2 v_{\alpha,\beta}^\delta = A^* (y_\delta - A(v_{\alpha,\beta}^\delta + u_{\alpha,\beta}^\delta)).$$

Due to our choice of β ($\beta > \|B^{-2}\| \|A\|$), it gives us the following bound

$$\|v_{\alpha,\beta}^\delta\| \leq \|y_\delta - A(v_{\alpha,\beta}^\delta + u_{\alpha,\beta}^\delta)\| \leq c\delta.$$

Moreover, using the notation $x_\alpha^\delta = (\alpha\mathbb{I} + A^*A)^{-1}A^*y_\delta$ and (2.10) we can rewrite

$$u_{\alpha,\beta}^\delta = x_\alpha^\delta - (\alpha\mathbb{I} + A^*A)^{-1}A^*Av_{\alpha,\beta}^\delta.$$

In view of the discrepancy domain principle it holds

$$\begin{aligned} c\delta &= \|A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta) - y_\delta\| \\ &= \|Ax_\alpha^\delta - y_\delta + Av_{\alpha,\beta}^\delta - A(\alpha\mathbb{I} + A^*A)^{-1}A^*Av_{\alpha,\beta}^\delta\| \\ &\geq \|Ax_\alpha^\delta - y_\delta\| - \|A\|\|v_{\alpha,\beta}^\delta\|, \end{aligned}$$

which is the same as

$$\begin{aligned} \|Ax_\alpha^\delta - y_\delta\| &\leq c\delta + \|A\|\|v_{\alpha,\beta}^\delta\| \\ &\leq c\delta + \frac{1}{\beta} \|B^{-2}\| \|A\|^2 \|y_\delta - A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta)\| \\ &\leq \hat{c}\delta. \end{aligned}$$

Thus, if there are sets (α, β) that belong to the discrepancy domain and such that β is sufficiently large ($\beta > \|B^{-2}\| \|A\|^2$) then TP regularization x_α^δ with the same α as in the pair (α, β) meets the discrepancy principle with a constant $\hat{c} > 1$. Then from [22] it follows that for $x^\dagger = \varphi(A^*A)g$ such that $\frac{\sqrt{t}}{\varphi(t)}$ is a nondecreasing function, we have

$$\|x^\dagger - x_\alpha^\delta\| \leq c_1 \varphi(\theta_\varphi^{-1}(\delta)),$$

where the constant c_1 does not depend on δ and the order $O(\varphi(\theta_\varphi^{-1}(\delta)))$ cannot be improved in general.

Therefore, for (α, β) meeting the discrepancy principle with a sufficiently large β we have

$$\begin{aligned} \|x^\dagger - u_{\alpha,\beta}^\delta - v_{\alpha,\beta}^\delta\| &\leq \|x^\dagger - x_\alpha^\delta + (\alpha\mathbb{I} + A^*A)^{-1}A^*Av_{\alpha,\beta}^\delta - v_{\alpha,\beta}^\delta\| \\ &\leq \|x^\dagger - x_\alpha^\delta\| + \alpha \|(\alpha\mathbb{I} + A^*A)^{-1}\| \|v_{\alpha,\beta}^\delta\| \\ &\leq c_1 \varphi(\theta_\varphi^{-1}(\delta)) + c\delta \leq (c_1 + c) \varphi(\theta_\varphi^{-1}(\delta)), \end{aligned}$$

and the order $O(\varphi(\theta_\varphi^{-1}(\delta)))$ cannot in general be improved. \square

Remark 3.4. In the context of Theorem 3.1 and Theorem 3.3 one still needs to decide which of the parameters α, β should be taken large enough. If such a decision is made then the theorems guarantee the optimal order of accuracy provided that another parameter has been chosen such that $(\alpha, \beta) \in D(\delta)$. In section 5.1 we propose to address the issue about the choice of the larger parameter by combining the discrepancy domain principle with the heuristic quasi-optimality criterion.

4. Model function approximation for the discrepancy domain principle.

In the present section we discuss a numerical realization of the discrepancy domain principle based on the model function approximation [13, 15, 29, 17, 16].

For the standard one-parameter TP method it has been proposed in [13, 15, 29] to implement the discrepancy principle by approximating the discrepancy $\|Ax_\alpha^\delta - y_\delta\|$ locally by means of some simple model function $m(\alpha)$ of the parameter α . Then the underlying concept has been extended to the multiparameter regularization. We may refer to [17, 16] for more details on this issue.

However, let us shortly mention that the existing approaches to the construction of a model function presuppose that values of the regularization parameters are smaller than 1. Therefore, they cannot be directly used in our case since, as can be seen from the above theorems, the order optimality is achieved under the assumption that $(\alpha, \beta) \in D(\delta)$ and one of the parameters is sufficiently large. This forces us to consider a special form of the model function which allows for an approximation of the corresponding regions of the parameters, and which is able to satisfy the specifics of the presented multipenalty scheme. For the subsequent analysis we need the following proposition which can be proven similarly to [15].

PROPOSITION 4.1. *The minimizers $u_{\alpha,\beta}^\delta, v_{\alpha,\beta}^\delta$ are differentiable as functions of $\alpha, \beta > 0$.*

Now let $F(\alpha, \beta)$ denote the minimal value of the functional (2.9) for given $\alpha, \beta > 0$, i.e., $F(\alpha, \beta) := \Phi(\alpha, \beta; u_{\alpha,\beta}^\delta, v_{\alpha,\beta}^\delta)$. The partial derivatives of the corresponding function are derived in the following lemma.

LEMMA 4.2. *The first order partial derivatives of $F(\alpha, \beta)$ are given by*

$$\frac{\partial F}{\partial \alpha}(\alpha, \beta) = \|u_{\alpha,\beta}^\delta\|^2, \quad \frac{\partial F}{\partial \beta}(\alpha, \beta) = \|Bv_{\alpha,\beta}^\delta\|^2.$$

Proof. First it is useful to observe that for any function f of the form $f(t) = \|Qx_t - g\|^2$ its derivative can be represented as

$$\frac{df}{dt} = 2 \langle Qx_t - g, Qx'_t \rangle,$$

where x'_t is the derivative of x_t as a function of the index t .

Using this observation, we have

$$\begin{aligned} \frac{\partial F}{\partial \alpha}(\alpha, \beta) &= 2 \left\langle A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta) - y_\delta, A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta)'_\alpha \right\rangle + 2\alpha \left\langle u_{\alpha,\beta}^\delta, (u_{\alpha,\beta}^\delta)'_\alpha \right\rangle \\ &\quad + \|u_{\alpha,\beta}^\delta\|^2 + 2\beta \left\langle Bv_{\alpha,\beta}^\delta, B(v_{\alpha,\beta}^\delta)'_\alpha \right\rangle \\ &= \|u_{\alpha,\beta}^\delta\|^2 + 2 \left\langle A^*A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta) - A^*y_\delta + \alpha u_{\alpha,\beta}^\delta, (u_{\alpha,\beta}^\delta)'_\alpha \right\rangle \\ &\quad + 2 \left\langle A^*A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta) - A^*y_\delta + \beta B^2 v_{\alpha,\beta}^\delta, (v_{\alpha,\beta}^\delta)'_\alpha \right\rangle. \end{aligned}$$

Observe also that (2.10), (2.11) can be rewritten in the variational form as

$$(4.1) \quad \begin{cases} \left\langle A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta), Ag \right\rangle + \alpha \left\langle u_{\alpha,\beta}^\delta, g \right\rangle = \langle y_\delta, Ag \rangle, \\ \left\langle A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta), Ag \right\rangle + \beta \left\langle B^2 v_{\alpha,\beta}^\delta, g \right\rangle = \langle y_\delta, Ag \rangle \end{cases}$$

for all $g \in X$.

Then, by taking $g = (u_{\alpha,\beta}^\delta)'_\alpha$ in the first equation and $g = (v_{\alpha,\beta}^\delta)'_\alpha$ in the second one of (4.1) and plugging them in the above representation for $\frac{\partial F}{\partial \alpha}(\alpha, \beta)$, we get that $\frac{\partial F}{\partial \alpha}(\alpha, \beta) = \|u_{\alpha,\beta}^\delta\|^2$.

Analogously, one can derive the representation for $\frac{\partial F}{\partial \beta}(\alpha, \beta)$. \square

By definition (2.9) and Lemma 4.2, we can rewrite (3.2) for $(\alpha, \beta) \in D(\delta)$ as

$$(4.2) \quad F(\alpha, \beta) - \alpha \frac{\partial F}{\partial \alpha} - \beta \frac{\partial F}{\partial \beta} = c^2 \delta^2.$$

Note that by taking $g = u_{\alpha,\beta}^\delta$ in the first equation, and $g = v_{\alpha,\beta}^\delta$ in the second equation of (4.1) and summing them up, we obtain

$$\alpha \|u_{\alpha,\beta}^\delta\|^2 + \beta \|Bv_{\alpha,\beta}^\delta\|^2 + \|A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta)\|^2 = \langle y_\delta, A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta) \rangle.$$

Then, using this equality, we can derive

$$(4.3) \quad \begin{aligned} F(\alpha, \beta) &= \|A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta) - y_\delta\|^2 + \alpha \|u_{\alpha,\beta}^\delta\|^2 + \beta \|Bv_{\alpha,\beta}^\delta\|^2 \\ &= \|A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta)\|^2 - 2 \langle A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta), y_\delta \rangle \\ &\quad + \|y_\delta\|^2 + \alpha \|u_{\alpha,\beta}^\delta\|^2 + \beta \|Bv_{\alpha,\beta}^\delta\|^2 \\ &= \|y_\delta\|^2 - \|A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta)\|^2 - \alpha \|u_{\alpha,\beta}^\delta\|^2 - \beta \|Bv_{\alpha,\beta}^\delta\|^2. \end{aligned}$$

In the following, we discuss how one can construct a simple parameterized function, the so-called *model function* $m(\alpha, \beta)$, which preserves the main properties of the function $F(\alpha, \beta)$. To this end, we first derive a new form of the model function which provides an approximation taking into account our specific interest in the parameter choice. Then we present necessary specifications for each of the two cases, when either α or β is sufficiently large.

4.1. Model function construction. In the following, we make the technical assumption that

$$\|y_\delta\|^2 - \|A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta)\|^2 = C_1 \delta^2.$$

This assumption can be rigorously justified in the regime of $\delta \in (\delta_0, 1)$, where $\delta_0 \approx 0$, $\delta_0 > 0$. In fact, one can find a positive number $C = C(\delta_0)$ such that

$$\begin{aligned} \|y_\delta\|^2 - \|A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta)\|^2 &\leq C(\delta_0) (\|y_\delta\| - \|A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta)\|)^2 \\ &\leq C(\delta_0) \|y_\delta - A(u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta)\|^2 \\ &\leq C(\delta_0) c \delta^2. \end{aligned}$$

Thus, our technical assumption holds true with $C_1 = C(\delta_0)c$. Then we get the approximate formula

$$F(\alpha, \beta) \approx C_1 \delta^2 - \alpha \frac{\partial F}{\partial \alpha}(\alpha, \beta) - \beta \frac{\partial F}{\partial \beta}(\alpha, \beta).$$

Now we want to derive a surrogate function $m(\alpha, \beta)$ for which the above formula is exact such that we define

$$m(\alpha, \beta) = C_1\delta^2 - \alpha \frac{\partial m}{\partial \alpha}(\alpha, \beta) - \beta \frac{\partial m}{\partial \beta}(\alpha, \beta).$$

Solving this partial differential equation we obtain a parametric family of the solutions

$$(4.4) \quad m(\alpha, \beta) = C_1\delta^2 + \frac{C_2}{\alpha} + \frac{C_3}{\beta} + \frac{C_4}{\sqrt{\alpha\beta}},$$

where C_1, C_2, C_3, C_4 are constants to be determined. We refer to the function (4.4) as the four-parameter model function.

We want to realize an approximate solution to (3.2) by an iterative procedure which, using the model functions of the form (4.4), produces sequences $\{\beta_k(\alpha)\}, k = 1, 2, \dots$, with the fixed $\alpha = \alpha^* > 1$ and $\{\alpha_k(\beta)\}, k = 1, 2, \dots$, with $\beta = \beta^* > 1$.

To this end, we assume that $\alpha = \alpha^*$, $\beta = \beta_k(\alpha^*)$, or $\beta = \beta^*$, $\alpha = \alpha_k(\beta^*)$, have been already found, and the minimizers $u_{\alpha,\beta}^\delta$, $v_{\alpha,\beta}^\delta$ are given by the formulas (2.10), (2.11) for these values of the parameters. Then we determine C_1, \dots, C_4 in such a way that the corresponding function (4.4) interpolates the function $F(\alpha, \beta)$ and its first order partial derivatives, as well as the mixed derivative at the given point (α, β) . Then, it means that the parameters C_1, \dots, C_4 should solve the system

$$(4.5) \quad \begin{cases} m(\alpha, \beta) = C_1\delta^2 + \frac{C_2}{\alpha} + \frac{C_3}{\beta} + \frac{C_4}{\sqrt{\alpha\beta}} = F(\alpha, \beta), \\ \frac{\partial m}{\partial \beta}(\alpha, \beta) = -\frac{C_3}{\beta^2} - \frac{1}{2} \frac{C_4}{\sqrt{\alpha\beta^3}} = \frac{\partial F}{\partial \beta}(\alpha, \beta) = \left\| Bv_{\alpha,\beta}^\delta \right\|^2, \\ \frac{\partial m}{\partial \alpha}(\alpha, \beta) = -\frac{C_2}{\alpha^2} - \frac{1}{2} \frac{C_4}{\sqrt{\alpha^3\beta}} = \frac{\partial F}{\partial \alpha}(\alpha, \beta) = \left\| u_{\alpha,\beta}^\delta \right\|^2, \\ \frac{\partial^2 m}{\partial \alpha \partial \beta}(\alpha, \beta) = \frac{1}{4} \frac{C_4}{\sqrt{\alpha^3\beta^3}} = \frac{\partial^2 F}{\partial \alpha \partial \beta}(\alpha, \beta) = 2 \left\langle u_{\alpha,\beta}^\delta, \frac{\partial u_{\alpha,\beta}^\delta}{\partial \beta}(\alpha, \beta) \right\rangle. \end{cases}$$

For clarity, below we derive the formula for the calculation of $\frac{\partial u_{\alpha,\beta}^\delta}{\partial \beta}$. By (2.10) we have that

$$\frac{\partial u_{\alpha,\beta}^\delta}{\partial \beta} = -(\alpha \mathbb{I} + A^* A)^{-1} A^* A \frac{\partial v_{\alpha,\beta}^\delta}{\partial \beta}.$$

At first observe that the derivative of functions of the form $z(\beta) = (\beta B^2 + C)^{-1} g$ is given by

$$\frac{dz}{d\beta} = -(\beta B^2 + C)^{-1} B^2 (\beta B^2 + C)^{-1} g.$$

Then, using this fact, we can easily deduce that

$$(4.6) \quad \begin{aligned} \frac{\partial v_{\alpha,\beta}^\delta}{\partial \beta} &= -\alpha (\beta B^2 + \alpha A^* A (\alpha \mathbb{I} + A^* A)^{-1})^{-1} \\ &\quad \times B^2 (\beta B^2 + \alpha A^* A (\alpha \mathbb{I} + A^* A)^{-1})^{-1} (\alpha \mathbb{I} + A^* A)^{-1} A^* y_\delta. \end{aligned}$$

Combining (4.6) with (4.5) and solving the above system of equations, we finally derive the formulas for the unknown coefficients at any point $(\alpha, \beta) \in D(\delta)$:

$$(4.7) \quad \begin{cases} C_1(\alpha, \beta) = \left(\|y_\delta\|^2 - \|A(u_{\alpha, \beta}^\delta + v_{\alpha, \beta}^\delta)\|^2 \right) / \delta^2, \\ C_2(\alpha, \beta) = -\alpha^2 \|u_{\alpha, \beta}^\delta\|^2 - \frac{1}{2} C_4 \sqrt{\frac{\alpha}{\beta}}, \\ C_3(\alpha, \beta) = -\beta^2 \|Bv_{\alpha, \beta}^\delta\|^2 - \frac{1}{2} C_4 \sqrt{\frac{\beta}{\alpha}}, \\ C_4(\alpha, \beta) = 8\sqrt{\alpha^5 \beta^3} \left\langle u_{\alpha, \beta}^\delta, (\alpha\mathbb{I} + A^* A)^{-1} A^* A (\beta B^2 + \alpha A^* A(\alpha\mathbb{I} + A^* A)^{-1})^{-1} B^2 \right. \\ \left. \times (\beta B^2 + \alpha A^* A(\alpha\mathbb{I} + A^* A)^{-1})^{-1} (\alpha\mathbb{I} + A^* A)^{-1} A^* y_\delta \right\rangle. \end{cases}$$

Then the model function (4.4) with the obtained coefficients (4.7) is used to find an updated value of the regularization parameter $\beta = \beta_{k+1} = \beta_{k+1}(\alpha^*)$, $\alpha^* > 1$, i.e., by solving for β the equation

$$m(\alpha^*, \beta) - \alpha^* \frac{\partial m}{\partial \alpha}(\alpha^*, \beta) - \beta \frac{\partial m}{\partial \beta}(\alpha^*, \beta) = c^2 \delta^2,$$

which corresponds to the model function approximation of the discrepancy principle (4.2). It is easy to see that this equation is equivalent to a quadratic equation, and its solutions $\beta = \beta_{k+1}$, if they exist, are given as

$$(4.8) \quad \beta_{k+1} = \beta_{k+1}^{1,2} = \frac{16C_3^2}{\left(-\frac{2C_4}{\sqrt{\alpha}} \pm \sqrt{\frac{4C_4^2}{\alpha} - 8C_3\left(\frac{2C_2}{\alpha} + (C_1 - c^2)\delta^2\right)} \right)^2}.$$

Following a similar path, we can update the value of the regularization parameter $\alpha = \alpha_{k+1} = \alpha_{k+1}(\beta^*)$, $\beta^* > 1$, by solving w.r.t. α the equation of the approximate discrepancy principle

$$m(\alpha, \beta^*) - \alpha \frac{\partial m}{\partial \alpha}(\alpha, \beta^*) - \beta^* \frac{\partial m}{\partial \beta}(\alpha, \beta^*) = c^2 \delta^2,$$

whose solutions are given as

$$(4.9) \quad \alpha_{k+1} = \alpha_{k+1}^{1,2} = \frac{16C_2^2}{\left(-\frac{2C_4}{\sqrt{\beta}} \pm \sqrt{\frac{4C_2^2}{\beta} - 8C_2\left(\frac{2C_3}{\beta} + (C_1 - c^2)\delta^2\right)} \right)^2}.$$

Finally, we can formulate a parallel iterative algorithm based on the model function approximation in the form of an alternating procedure as follows:

Step 0. Given δ , c , y_δ , A , and α_0 , β_0 : $(\alpha_0, \beta_0) \notin D(\delta)$, set $k = 0$.

- Step 1. (1) Fix $\alpha^* > 1$ and calculate $x_{\alpha^*, \beta_k}^\delta = u_{\alpha^*, \beta_k}^\delta + v_{\alpha^*, \beta_k}^\delta$; calculate the coefficients $C_1(\alpha^*, \beta_k)$, $C_2(\alpha^*, \beta_k)$, $C_3(\alpha^*, \beta_k)$, and $C_4(\alpha^*, \beta_k)$ in accordance with (4.7), where $\alpha = \alpha^*$, $\beta = \beta_k$; update $\beta = \beta_{k+1}$ in accordance with (4.8), where we choose among $\beta_{k+1}^{1,2}$ the one that belongs to $(0, 1)$.
(2) Calculate $x_{\alpha^*, \beta_{k+1}}^\delta$ by solving (2.10) and (2.11) with $\alpha = \alpha^*$ and $\beta = \beta_{k+1}$.
(3) GO to Step 2 if the stopping criteria $\|Ax_{\alpha^*, \beta_{k+1}}^\delta - y_\delta\| \leq c\delta$ is satisfied; otherwise set $k = k + 1$, GOTO (1).

- Step 2. (1) Fix $\beta^* > 1$ and calculate $x_{\alpha_k, \beta^*}^\delta = u_{\alpha_k, \beta^*}^\delta + v_{\alpha_k, \beta^*}^\delta$; calculate the coefficients $C_1(\alpha_k, \beta^*)$, $C_2(\alpha_k, \beta^*)$, $C_3(\alpha_k, \beta^*)$, and $C_4(\alpha_k, \beta^*)$ in accordance with (4.7), where $\alpha = \alpha_k$, $\beta = \beta^*$; update $\alpha = \alpha_{k+1}$ in accordance with (4.9), where we choose among $\alpha_{k+1}^{1,2}$ the one that belongs to $(0, 1)$.
(2) Calculate $x_{\alpha_{k+1}, \beta^*}^\delta$ by solving (2.10) and (2.11) with $\alpha = \alpha_{k+1}$ and $\beta = \beta^*$.
(3) STOP if the stopping criteria $\|Ax_{\alpha_{k+1}, \beta^*}^\delta - y_\delta\| \leq c\delta$ is satisfied; otherwise set $k = k + 1$, GOTO (1).

Remark 4.3. Note that because the definitions of β_{k+1} (4.8) and α_{k+1} (4.9) involve the solution of the quadratic equations at each iteration, it may not always be straightforward to pick β_{k+1} or α_{k+1} : it may happen that an equation has either two or no solutions. In the first case, when two solutions exist and one of them is positive, one naturally takes the smallest positive root as the new parameter. In the latter case, when no positive solution exists, the following approximation formulas for β_{k+1} and α_{k+1} can be used:

$$\beta_{k+1} = \frac{4\alpha^* C_3^2}{C_4^2},$$

$$\alpha_{k+1} = \frac{4\beta^* C_2^2}{C_4^2},$$

which are the least squares solutions of the equations $G^m(\alpha^*, \beta) = c^2\delta^2$ and $G^m(\alpha, \beta^*) = c^2\delta^2$, respectively.

In our numerical experiments it never occurred that there were no positive solutions to define $\beta_{k+1}, \alpha_{k+1}$.

Remark 4.4. Potentially Newton-type reconstruction methods could also be used to reconstruct the discrepancy domain. For instance, the authors in [15] considered a modification of the original Newton method to solve the damped discrepancy principle. However, in our case the application of any Newton-type method requires knowledge of the partial derivatives of $u_{\alpha, \beta}^\delta$ and $v_{\alpha, \beta}^\delta$, which in turn can be obtained by solving additionally four equations of the form (4.6) at each point. At the same time, employing the model function approach, we are asked for only one partial derivative $\frac{\partial v_{\alpha, \beta}^\delta}{\partial \beta}$, which makes each iteration step less expensive to perform.

4.2. Properties of the model function approximation. In this subsection we are going to show that the algorithm of the four-parameter model function approximation produces decreasing sequences of the regularization parameters $\{\alpha_k(\beta^*)\}$ with $\beta^* > 1$ and $\{\beta_k(\alpha^*)\}$ with $\alpha^* > 1$ provided that in each step the discrepancy is larger than a given threshold.

In each updating step the discrepancy function

$$G(\alpha, \beta) = \|A(u_{\alpha, \beta}^\delta + v_{\alpha, \beta}^\delta) - y_\delta\|^2$$

is approximated by the function

$$G^m(\alpha, \beta) = m(\alpha, \beta) - \alpha \frac{\partial m}{\partial \alpha}(\alpha, \beta) - \beta \frac{\partial m}{\partial \beta}(\alpha, \beta).$$

By definition

$$G(\alpha, \beta) = F(\alpha, \beta) - \alpha \frac{\partial F}{\partial \alpha} - \beta \frac{\partial F}{\partial \beta}$$

and for any $k = 0, 1, \dots$, we have

$$G(\alpha^*, \beta_k) = G^m(\alpha^*, \beta_k), \quad G(\alpha_k, \beta^*) = G^m(\alpha_k, \beta^*).$$

Now we show that the sequences of the parameters produced by the model function approximation are decreasing with k .

THEOREM 4.5. *Assume that for (α^*, β_k) we have $\|A(u_{\alpha^*, \beta_k}^\delta + v_{\alpha^*, \beta_k}^\delta) - y^\delta\| > c\delta$. If $\beta = \beta_{k+1}$ is given by the formula (4.8) as the positive solution of the equation $G^m(\alpha^*, \beta) = c^2\delta^2$ corresponding to the model function approximation of the discrepancy principle, then $\beta_{k+1} < \beta_k$.*

Proof. Observe that $g(\beta) := G^m(\alpha^*, \beta)$ is an increasing function of β since

$$\begin{aligned} \frac{dg(\beta)}{d\beta} &= \frac{\partial m}{\partial \beta}(\alpha^*, \beta) - \alpha^* \frac{\partial^2 m}{\partial \alpha \partial \beta}(\alpha^*, \beta) - \frac{\partial m}{\partial \beta}(\alpha^*, \beta) - \beta \frac{\partial^2 m}{\partial \beta^2}(\alpha^*, \beta) \\ &= -\frac{1}{4} \frac{C_4}{\sqrt{\alpha^* \beta^3}} - \beta \left(2 \frac{C_3}{\beta^3} + \frac{3}{4} \frac{C_4}{\sqrt{\alpha^* \beta^5}} \right) \\ &= -\frac{1}{4} \frac{C_4}{\sqrt{\alpha^* \beta^3}} - \frac{1}{\beta^2} \left(-2\beta^2 \|Bv_{\alpha^*, \beta}^\delta\|^2 - C_4 \sqrt{\frac{\beta}{\alpha^*}} \right) \\ &\quad - \frac{3}{4} \frac{C_4}{\sqrt{\alpha^* \beta^3}} = 2\|Bv_{\alpha^*, \beta}^\delta\|^2 > 0. \end{aligned}$$

Since β_{k+1} satisfies $g(\beta_{k+1}) = G^m(\alpha^*, \beta_{k+1}) = c^2\delta^2$, from $g(\beta_k) = G^m(\alpha^*, \beta_k) = G(\alpha^*, \beta_k) > c^2\delta^2$ and the monotonicity of $g(\beta)$, we have

$$\beta_{k+1} < \beta_k. \quad \square$$

A similar theorem is also valid for the case of $\alpha_{k+1}(\beta^*)$, $\beta^* > 1$.

THEOREM 4.6. *Assume that for (α_k, β^*) we have $\|A(u_{\alpha_k, \beta^*}^\delta + v_{\alpha_k, \beta^*}^\delta) - y^\delta\| > c\delta$. If $\alpha = \alpha_{k+1}$ is the minimal positive solution of the equation $G^m(\alpha, \beta^*) = c^2\delta^2$, then $\alpha_{k+1} < \alpha_k$.*

Remark 4.7. From the above theorems it follows that the discrepancy domain can be approximately reconstructed by taking grids of the parameters

$$(4.10) \quad \begin{aligned} \alpha \in Q_N^\alpha &= \{\alpha = \alpha_i = \alpha_0 q^i, i = 0, 1, 2, \dots, N\}, \quad q > 1, \\ \beta \in P_M^\beta &= \{\beta = \beta_j = \beta_0 p^j, j = 0, 1, 2, \dots, M\}, \quad p > 1. \end{aligned}$$

Then one constructs two sequences $\{\alpha_k(\beta^*)\}$ for each $\beta^* = \beta_j > 1$, $\beta^* \in P_M^\beta$ and $\{\beta_k(\alpha^*)\}$ for each $\alpha^* = \alpha_i > 1$, $\alpha^* \in Q_N^\alpha$. The constructed points $(\alpha_k(\beta^*), \beta^*)$ and $(\alpha^*, \beta_k(\alpha^*))$ will converge and, as numerical experiments show, lie in the discrepancy domain.

5. Numerical realization and illustrations. In this section we provide a computational confirmation that, as predicted by Theorems 3.1 and 3.3, multipenalty regularization may perform better than the corresponding one-parameter counterpart. The regularization parameters for both one-parameter regularization schemes (2.3) and (2.6) are chosen in accordance with the discrepancy principle, whereas as the parameter choice rule for multipenalty regularization we consider the newly introduced discrepancy domain principle in combination with the quasi-optimality criterion. The latter was originally proposed in [28] and has been recently advocated in

[14]. Moreover, we show that the discrepancy domain can be accurately and quickly approximated using the model function approach, introduced in the previous section.

Finally, motivated by some positive results in [17], we also consider the three-penalty regularization scheme as a possible step towards generalization of the given multipenalty regularization approach.

5.1. Discrepancy domain principle and quasi-optimality criterion. We start the discussion of the numerical results with the realization of the discrepancy domain principle in combination with the quasi-optimality criterion. Recall that from Theorems 3.1 and 3.3 it follows that the application of the multipenalty regularization leads to an order-optimal solution $x_{\alpha,\beta}^\delta = u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta$ that is achieved either for $(\alpha, \beta) \in D(\delta)$, $\alpha > 1$ or $(\alpha, \beta) \in D(\delta)$, $\beta > 1$.

To find the pairs (α, β) which allow us to achieve this order-optimal reconstruction we consider the two grids of the parameters (4.10) and search for those (α, β) which satisfy the discrepancy domain principle (3.1).

Then, one would ideally find the pairs (α_{i_*}, β_J) , $(\alpha_I, \beta_{j_*}) \in D(\delta)$ such that $\alpha_I, \beta_J > 1$ and

$$\begin{aligned}\|x^\dagger - x_{\alpha_{i_*}, \beta_J}^\delta\| &= \min \left\{ \|x^\dagger - x_{\alpha_i, \beta_j}^\delta\| : (\alpha_i, \beta_j) \in D(\delta), \beta_j > 1 \right\}, \\ \|x^\dagger - x_{\alpha_I, \beta_{j_*}}^\delta\| &= \min \left\{ \|x^\dagger - x_{\alpha_i, \beta_j}^\delta\| : (\alpha_i, \beta_j) \in D(\delta), \alpha_i > 1 \right\},\end{aligned}$$

and then choose the one that allows the most accurate reconstruction, i.e.,

$$(\alpha_+, \beta_+) = \begin{cases} (\alpha_{i_*}, \beta_J) & \text{if } \|x^\dagger - x_{\alpha_{i_*}, \beta_J}^\delta\| \leq \|x^\dagger - x_{\alpha_I, \beta_{j_*}}^\delta\|, \\ (\alpha_I, \beta_{j_*}) & \text{if } \|x^\dagger - x_{\alpha_{i_*}, \beta_J}^\delta\| > \|x^\dagger - x_{\alpha_I, \beta_{j_*}}^\delta\|. \end{cases}$$

Unfortunately, since x^\dagger is unknown, one cannot determine such an ideal pair of the parameters exactly. However, due to the belief [8] that in the quasi-optimality criterion [28] for the one-parameter regularization schemes the values

$$\|x_{\alpha_i}^\delta - x_{\alpha_{i-1}}^\delta\| \quad \text{or} \quad \|x_{\beta_j, B}^\delta - x_{\beta_{j-1}, B}^\delta\|$$

serve as “surrogates” of

$$\|x^\dagger - x_{\alpha_i}^\delta\| \quad \text{or} \quad \|x^\dagger - x_{\beta_j, B}^\delta\|,$$

one can select $\alpha = \alpha_{i_*} \in Q_N^\alpha$, $\beta = \beta_{j_*} \in P_M^\beta$ such that

$$\|x_{\alpha_{i_*}}^\delta - x_{\alpha_{i*-1}}^\delta\| = \min \left\{ \|x_{\alpha_i}^\delta - x_{\alpha_{i-1}}^\delta\|, i = 1, 2, \dots, N \right\}$$

or

$$\|x_{\beta_{j_*}, B}^\delta - x_{\beta_{j*-1}, B}^\delta\| = \min \left\{ \|x_{\beta_j, B}^\delta - x_{\beta_{j-1}, B}^\delta\|, j = 1, 2, \dots, M \right\}.$$

Thus, we employ the idea of the quasi-optimality criterion to use the above-mentioned “surrogates” as the performance indicators and choose in the discrepancy domain the pairs (α_{i_*}, β_J) and (α_I, β_{j_*}) that allow the minimum distance between

the regularized solutions corresponding to two successive values of the regularization parameters:

$$\begin{aligned}\|x_{\alpha_{i_*}, \beta_J}^\delta - x_{\alpha_{i_*-1}, \beta_J}^\delta\| &= \min \left\{ \|x_{\alpha_i, \beta_j}^\delta - x_{\alpha_{i-1}, \beta_j}^\delta\| : (\alpha_i, \beta_j) \in D(\delta), \beta_j > 1 \right\}, \\ \|x_{\alpha_I, \beta_{j_*}}^\delta - x_{\alpha_I, \beta_{j_*-1}}^\delta\| &= \min \left\{ \|x_{\alpha_i, \beta_j}^\delta - x_{\alpha_i, \beta_{j-1}}^\delta\| : (\alpha_i, \beta_j) \in D(\delta), \alpha_i > 1 \right\}.\end{aligned}$$

Then, similarly to the ideal case we choose the pair of the parameters as follows:

$$(\alpha_+, \beta_+) = \begin{cases} (\alpha_{i_*}, \beta_J), & \text{if } \|x_{\alpha_{i_*}, \beta_J}^\delta - x_{\alpha_{i_*-1}, \beta_J}^\delta\| \leq \|x_{\alpha_I, \beta_{j_*}}^\delta - x_{\alpha_I, \beta_{j_*-1}}^\delta\|, \\ (\alpha_I, \beta_{j_*}), & \text{if } \|x_{\alpha_{i_*}, \beta_J}^\delta - x_{\alpha_{i_*-1}, \beta_J}^\delta\| > \|x_{\alpha_I, \beta_{j_*}}^\delta - x_{\alpha_I, \beta_{j_*-1}}^\delta\|. \end{cases}$$

As one can see below, such a combination of the discrepancy domain principle and the quasi-optimality criterion is a quite flexible tool for choosing the regularization parameters. Moreover, it is easily implementable and its computational efficiency is justified with the use of the model function approximation approach, presented in the previous section.

5.2. Numerical illustrations and comparisons: Operators with known singular value expansion. Similarly to [1, 26] in our first numerical experiment we consider compact operators A and B^{-1} that are related as

$$(5.1) \quad A = \sum_i a_i \langle \psi_i, \cdot \rangle \varphi_i, \quad B^{-1} = \sum_i b_i^{-1} \langle \psi_i, \cdot \rangle \psi_i,$$

where $\{a_i\}, \{b_i\}$ denote sets of eigenvalues of the self-adjoint operators $(A^* A)^{1/2}$ and B , correspondingly.

Note that the knowledge of the singular value expansion of the operators allows us to verify easily whether the link condition (2.7) is violated or not.

In the first experiments the operators A and B are given as diagonal matrices of the size n . The matrix corresponding to the operator A has diagonal elements $a_i = i^{-r}$, $i = 1, 2, \dots, n$, $n = 50$, $r = 3$. Further, we assume that the source condition (2.5) is satisfied with $\varphi(t) = t^p$, $p = 4$, and the solution x^\dagger is given in the form of the n -dimensional vector

$$(5.2) \quad x^\dagger = (A^* A)^4 g,$$

where g is a random vector whose components are uniformly distributed on $[0, 1]$ and such that $\|g\| = 10$; here and below $\|\cdot\|$ means the standard norm in the n -dimensional Euclidean space \mathbb{R}^n . Then the exact right-hand side is produced as $y = Ax^\dagger$.

Noisy data y_δ are simulated in the form $y_\delta = y + \xi$, where $\xi = \delta \frac{\epsilon}{\|\epsilon\|}$ and ϵ is a random vector with uniformly distributed components. Both vectors g and ϵ are generated 100 times, so that we have 100 problems of the form (2.1) with noisy data y_δ , and the noise level δ is given as $\delta = 0.01\|Ax^\dagger\|$ that corresponds to 1% of data noise.

In accordance with the theory, under the source condition (5.2) TP regularization may suffer from the saturation. On the other hand, this effect can be relaxed by using Tikhonov regularization with a proper choice of the regularization operator B for which the condition (2.7) is satisfied. At first, we choose the self-adjoint operator B such that the corresponding diagonal matrix has the elements

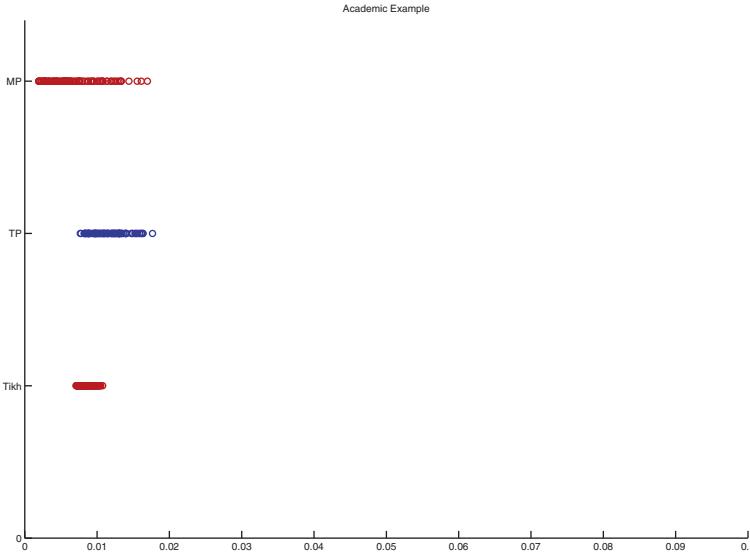

FIG. 1. *Numerical illustration (first experiment).* The figure presents relative errors (circles) for 100 simulations of y_δ with 1% noise.

TABLE 1

Numerical illustration (first experiment). Statistical performance measures for the regularized approximations $x_{\alpha,\beta}^\delta$, x_α^δ , $x_{\beta,B}^\delta$ and 100 simulations of y_δ with 1% noise.

	Mean RE	Median RE	Standard deviation RE	Mean parameter
$x_{\alpha,\beta}^\delta$	0.0069	0.0060	0.0036	$\alpha = 56.05, \beta = 0.002$
x_α^δ	0.0117	0.0114	0.0024	0.009
$x_{\beta,B}^\delta$	0.0086	0.086	0.0009	0.009

$b_{ii} = b_i = i$, $i = 1, 2, \dots, n$. For the considered A , the chosen operator B satisfies (2.7) with $s = 3$. In the experiments, we use the discrepancy domain principle in combination with the quasi-optimality criterion for multi-penalty regularization and the classical discrepancy principle for the one-parameter counterparts. In all cases grids of the parameters are given by (4.10) with the initial parameters $\alpha_0 = \beta_0 = 10^{-4}$, $q = p = 1.25$, and $N = M = 60$.

To assess the obtained results and compare the performance of the considered regularization schemes, we measure the relative error (RE)

$$\frac{\|x - x^\dagger\|}{\|x^\dagger\|}$$

for $x = x_{\alpha,\beta}^\delta$, $x = x_\alpha^\delta$, and $x = x_{\beta,B}^\delta$.

The results are displayed in Figure 1, where each circle represents a relative error in solving the problems with one of 100 simulated data, for each of the three regularization methods: multipenalty regularization (MP), TP regularization (TP), and Tikhonov regularization (Tikh).

Moreover, in Table 1 the statistical measures such as the mean, the median, and the standard deviation of the relative error, as well as the mean values of the regularization parameters are given for each of the methods.

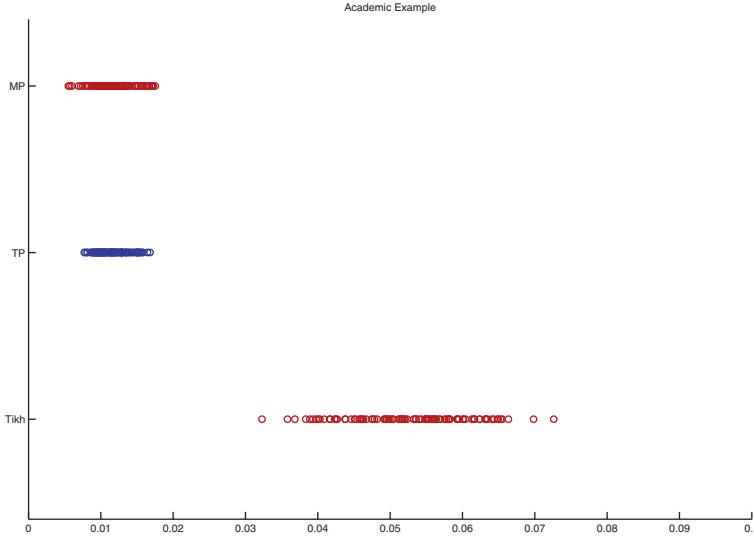

FIG. 2. *Numerical illustration (second experiment). The figure presents relative errors (circles) for 100 simulations of y_δ with 1% noise.*

TABLE 2

Numerical illustration (second experiment). Statistical performance measures for the regularized approximations $x_{\alpha,\beta}^\delta$, x_α^δ , $x_{\beta,B}^\delta$ and 100 simulations of y_δ with 1% noise.

	Mean RE	Median RE	Standard deviation RE	Mean parameter
$x_{\alpha,\beta}^\delta$	0.0117	0.0115	0.0029	$\alpha = 0.0064, \beta = 56.05$
x_α^δ	0.0117	0.0114	0.0022	0.009
$x_{\beta,B}^\delta$	0.0529	0.0535	0.0083	0.0116

On the other hand, if we consider the operator B , corresponding to the diagonal matrix with elements

$$b_i = \begin{cases} i, & i = 1, 3, \dots, 2j-1, \\ 1/i, & i = 2, 4, \dots, 2j, j = n/2, \end{cases}$$

then from Figure 2 and Table 2 we can see that the saturation cannot be relaxed by the Tikhonov method due to the fact that for the considered B the link condition (2.7) is violated ($\|B^{-s}\| \geq (n-1)^s \geq 1 \geq \|A\|$). At the same time, similar to what was observed in [26], we can see that multipenalty regularization equipped with the discrepancy domain principle and the quasi-optimality criterion shows performances at the level of the best single-penalty regularization.

Note that for the operators (5.1) and the solutions (5.2) we can verify the convergence rates indicated in Theorems 3.1 and 3.3. In the first experiment, when $b_i = i$, the solutions belong to the set (2.8) with $p = 24$, which is above the saturation level $p = s+2 = 5$ calculated according to Theorem 3.1. Therefore, in the considered situation the theorem guarantees us the accuracy of order $O(\delta^{\frac{s+2}{2s+2}}) = O(\delta^{5/8})$. In Table 3 we present the mean values of the numbers $C = \frac{\|x^\dagger - x_{\alpha,\beta}^\delta\|}{\delta^{5/8}}$ over 100 simulated solutions x^\dagger of the form (5.2) for different noise levels δ and parameters α, β chosen according to the discrepancy domain principle. As can be seen from the table the numbers exhibit a rather stable behavior supporting the statement of Theorem 3.1.

TABLE 3

Numerical illustration (first experiment). Estimation of the constants from the error bound (3.8) for different noise levels.

Noise level	$10^{-1.5}$	$10^{-1.8}$	$10^{-2.1}$	$10^{-2.4}$	$10^{-2.7}$	10^{-3}
Constant	0.2321	0.1860	0.1616	0.1347	0.1206	0.1190

TABLE 4

Numerical illustration (second experiment). Estimation of the constants from the error bound (3.3) for different noise levels.

Noise level	$10^{-1.5}$	$10^{-1.8}$	$10^{-2.1}$	$10^{-2.4}$	$10^{-2.7}$	10^{-3}
Constant	0.2171	0.3067	0.4332	0.6119	0.8644	1.2210

In the second experiment, the link condition (2.7) is violated and in view of the saturation of the discrepancy principle and TP regularization itself, we can expect only the accuracy of order $O(\delta^{1/2})$. The behavior of the mean values of the numbers $C = \frac{\|x^\dagger - x_{\alpha,\beta}^\delta\|}{\delta^{1/2}}$ for different δ 's is reflected in Table 4 and also can be accepted as evidence supporting the theory.

5.3. Numerical illustrations and comparisons: First kind Fredholm integral equations. In this subsection we are going to demonstrate that the compensatory property of multipenalty regularization or even improvement in the performance can be observed in a more general case, when the singular value expansion of the operators is not known. In such a case it may be hard to check the link condition (2.7). On the other hand, as Figure 2 shows, Tikhonov regularization (2.6) alone may perform poorly if a link condition is not granted. From such a perspective, multipenalty scheme (2.9)–(2.11) can be seen as a tool to make the regularization more flexible and reliable.

Remark 5.1. One may think that in the case of the failing link condition the need for a compensatory property arises from restricting ourselves to the Tikhonov-type regularization, and the use of multipenalty regularization can be avoided by switching to usual single-parameter iterative regularization schemes, such as iterated Tikhonov regularization [8, p. 123].

Note that such iterative schemes are also oriented towards smoothness expressed in the form (2.5), but in contrast to TP regularization, the iterative schemes can guarantee an accuracy of order $O(\varphi(\theta_\psi^{-1}(\delta)))$ even in the case when the function $\frac{t}{\varphi(t)}$ is decreasing (see, e.g., [18, p. 82]).

But the point is that for a given problem (2.1) a source condition (2.5) may not be an adequate form of measuring the smoothness of x^\dagger . Then an iterative regularization scheme may be outperformed by multipenalty regularization (2.9)–(2.11) even if it uses a penalizing operator B for which the link condition is not granted.

We illustrate this on Figure 3, where iterated Tikhonov regularization of order 3 (IterTP) performs better than TP regularization, but both of them are outperformed by multipenalty regularization (2.9)–(2.11) and Tikhonov regularization (2.6) that are based on the penalizing operator for which we do not know whether the link condition is satisfied or not.

We would like to stress that the use of iterated Tikhonov regularization of order higher than 3 does not change the picture. The authors are grateful to the anonymous referee whose comment inspires this remark.

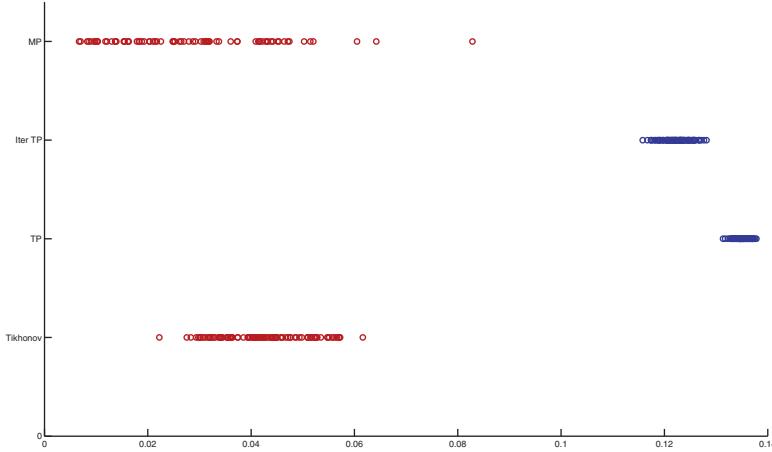

FIG. 3. Numerical illustration for the function $\text{ilaplace}(100, 1)$. The figure presents relative errors (circles) for 100 simulations of y_δ with 1% noise.

Similarly to [17, 26] we generate the test problems of the form (2.1) by using the functions $\text{shaw}(n)$ and $\text{ilaplace}(n, 1)$ from the MATLAB regularization toolbox [10]. These functions occur as the results of a discretization of the first kind Fredholm integral equation of the form

$$(5.3) \quad \int_a^b k(s, t)f(t)dt = g(s), \quad s \in [a, b],$$

with a known solution $f(t)$. As in the two previous experiments, the operator A and the solution x^\dagger are given as an $n \times n$ -matrix and n -dimensional vector respectively. The noisy data y_δ are simulated 100 times in the same way as above, i.e., $y_\delta = Ax^\dagger + \xi$ with the noise level δ corresponding to 1% of data noise.

Moreover, the penalizing operator is given as an $n \times n$ -matrix and defined as $B = (D^T D)^{1/2}$, where

$$(5.4) \quad D = \begin{pmatrix} 1 & -1 & & \\ & -1 & 1 & \\ & & \ddots & \\ & & & 1 & -1 \end{pmatrix}$$

is a discrete approximation of the first derivative on a regular grid with n points.

We perform the experiment with the function $\text{shaw}(n)$ that is a discretization of (5.3) with $a = -\pi/2$ and $b = \pi/2$. The kernel and the solution are given as

$$\begin{aligned} k(s, t) &= (\cos(s) + \cos(t))^2 \left(\frac{\sin(u)}{u} \right)^2, \quad u = \pi(\sin(s) + \sin(t)), \\ f(t) &= 2e^{-6(t-0.8)^2} + e^{-2(t+0.5)^2}. \end{aligned}$$

The corresponding equation (5.3) is discretized by a simple quadrature with n equidistant points. Similarly to [17, 26] we take $n = 100$. The results are displayed in Figure 4 and Table 5.

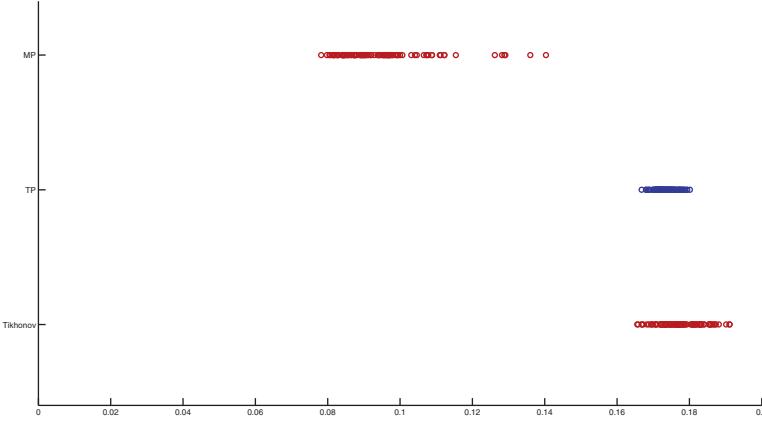

FIG. 4. Numerical illustration for the function $\text{shaw}(100)$. The figure presents relative errors (circles) for 100 simulations of y_δ with 1% noise.

TABLE 5

Numerical illustration for the function $\text{shaw}(100)$. Statistical performance measures for the regularized approximations $x_{\alpha,\beta}^\delta$, x_α^δ , $x_{\beta,B}^\delta$ and 100 simulations of y_δ with 1% noise.

	Mean RE	Median RE	Standard deviation RE	Mean parameter
$x_{\alpha,\beta}^\delta$	0.0950	0.0924	0.0140	$\alpha = 2.7784, \beta = 0.0007$
x_α^δ	0.1736	0.1732	0.0029	0.0011
$x_{\beta,B}^\delta$	0.1774	0.1768	0.0063	0.0146

TABLE 6

Numerical illustration for the function $\text{ilaplace}(100, 1)$. Statistical performance measures for the regularized approximations $x_{\alpha,\beta}^\delta$, x_α^δ , $x_{\beta,B}^\delta$ and 100 simulations of y_δ with 1% noise.

	Mean RE	Median RE	Standard deviation RE	Mean parameter
$x_{\alpha,\beta}^\delta$	0.0250	0.0209	0.0105	$\alpha = 2.7784, \beta = 0.0042$
x_α^δ	0.1323	0.1320	0.0005	0.0011
$x_{\beta,B}^\delta$	0.0421	0.0418	0.0027	0.0706

In the next experiment we consider the function $\text{ilaplace}(n, 1)$, which occurs in a discretization of the inverse Laplace transformation by means of the Gauss–Laguerre quadrature with n knots and corresponds to (5.3) with $a = 0$, $b = \infty$, $k(s, t) = e^{-st}$, $f(t) = e^{-t/2}$, $g(s) = (s + 1/2)^{-1}$.

For both problems the regularization parameters are chosen in accordance with the procedure described above, in which starting values of the parameter grids are given as $\alpha_0 = \beta_0 = 10^{-4}$, $q = p = 1.3$, $N = M = 40$.

In Figure 3 we show the relative errors produced by the three regularization methods. Moreover, Table 6 presents statistical information about the performance of the methods. Additionally, in Figure 3 one can see the relative errors produced by iterated Tikhonov regularization of order 3, as has been discussed in Remark 5.1.

Again superior performances of multipenalty regularization are observed even when it is not known a priori whether or not the link condition (2.7) is satisfied.

5.4. Three-penalty regularization. Motivated by some positive results with a three-parameter regularization [17], in this subsection we also consider the three-

penalty regularization with a componentwise penalization, in which the following form of the functional is considered:

$$(5.5) \quad \Phi_1(\alpha, \beta, \gamma; u, v, z) := \|A(u + v + z) - y_\delta\|_Y^2 + \alpha\|u\|_X^2 + \beta\|Bv\|_X^2 + \gamma\|Cz\|_X^2.$$

Then the regularized approximation $x_{\alpha, \beta, \gamma}^\delta$ is given as $x_{\alpha, \beta, \gamma}^\delta = u_{\alpha, \beta, \gamma}^\delta + v_{\alpha, \beta, \gamma}^\delta + z_{\alpha, \beta, \gamma}^\delta$, where $u_{\alpha, \beta, \gamma}^\delta$, $v_{\alpha, \beta, \gamma}^\delta$, and $z_{\alpha, \beta, \gamma}^\delta$ are the minimizers of the functional (5.5). In order to write down the formulas for the minimizers explicitly, we, at first, introduce two linear operators

$$\begin{aligned} M &= (\alpha\mathbb{I} + A^*A)^{-1}A^*A, \\ K &= B^2(\beta B^2 + \alpha M)^{-1}. \end{aligned}$$

Then the minimizers $u_{\alpha, \beta, \gamma}^\delta$, $v_{\alpha, \beta, \gamma}^\delta$, and $z_{\alpha, \beta, \gamma}^\delta$ of the functional $\Phi_1(\alpha, \beta, \gamma; u, v, z)$ have the form

$$\begin{aligned} u_{\alpha, \beta, \gamma}^\delta &= (\alpha\mathbb{I} + A^*A)^{-1}(A^*y_\delta - A^*A(v_{\alpha, \beta, \gamma}^\delta + z_{\alpha, \beta, \gamma}^\delta)), \\ v_{\alpha, \beta, \gamma}^\delta &= \alpha(\beta B^2 + \alpha M)^{-1}(\alpha\mathbb{I} + A^*A)^{-1}(A^*y_\delta - z_{\alpha, \beta, \gamma}^\delta), \\ z_{\alpha, \beta, \gamma}^\delta &= \left(KM + \frac{\gamma}{\alpha\beta}C^2\right)^{-1}K(\alpha\mathbb{I} + A^*A)^{-1}A^*y_\delta. \end{aligned}$$

In our numerical experiments the operators A , B are the same as before and the second penalizing operator $C = (\hat{D}^T\hat{D})^{1/2}$ is an $n \times n$ -matrix, where $(n-2) \times n$ -matrix

$$\hat{D} = \begin{pmatrix} -2 & 1 & & & \\ 1 & -2 & 1 & & \\ & & \ddots & & \\ & & & 1 & -2 \end{pmatrix}$$

is the discrete approximation to the second derivative operator on the regular grid with n points.

As in the previous subsection we consider the problems *shaw(100)* and *ilaplace(100, 1)* with 1% of noise in data to compare performances of the three-parameter regularization $x_{\alpha, \beta, \gamma}^\delta$ and the standard single-parameter ones x_α^δ , $x_{\gamma, C}^\delta$, and $x_{\beta, B}^\delta$.

Recall that for the one-parameter schemes we employ as a parameter choice rule the discrepancy principle and its corresponding modification for multipenalty method with starting parameters $\alpha_0 = \beta_0 = \gamma_0 = 10^{-4}$ and stepsize $q = p = l = 1.7$ for $\alpha \in Q_N^\alpha$, $\beta \in P_M^\beta$, and

$$\gamma \in S_W^\gamma = \{\gamma = \gamma_k = \gamma_0 l^k, k = 0, 1, 2, \dots, W\}, \quad l > 1.$$

The results are displayed in Figures 5 and 6 in which the notation is similar to ones in the figures above. Note that the relative error corresponding to Tikhonov regularization with the penalizing operator C is denoted as “Tikhonov 2” in the respective figures. For the sake of completeness, we also indicate in Tables 7 and 8 the mean, the median, and the standard deviation of the relative errors, as well as the mean values of the regularization parameters for all four regularization methods under consideration.

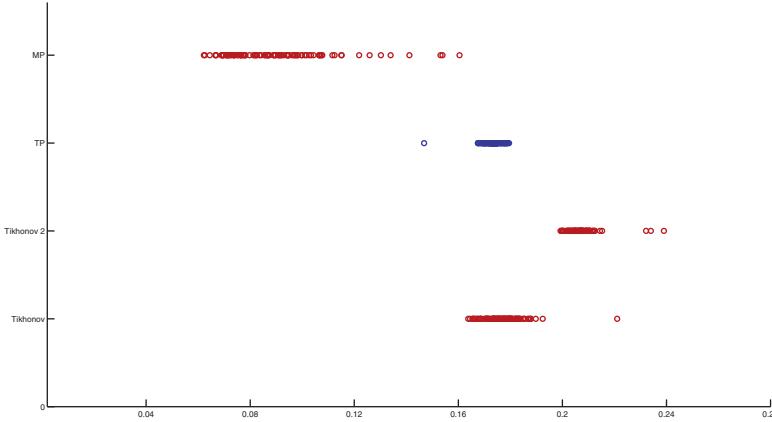

FIG. 5. Numerical illustration for the function $shaw(100)$. The figure presents relative errors (circles) for 100 simulations of y_δ with 1% noise.

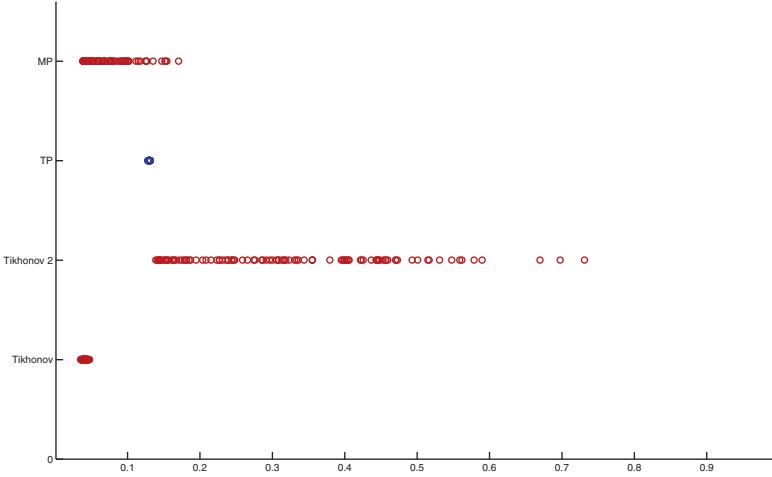

FIG. 6. Numerical illustration for the function $ilaplace(100, 1)$. The figure presents relative errors (circles) for 100 simulations of y_δ with 1% noise.

TABLE 7

Numerical illustration for the function $shaw(100)$. Statistical performance measures for the regularized approximations $x_{\alpha,\beta,\gamma}^\delta$, x_α^δ , $x_{\gamma,C}^\delta$, $x_{\beta,B}^\delta$, and 100 simulations of y_δ with 1% noise.

	Mean RE	Median RE	Standard deviation RE	Mean parameter
$x_{\alpha,\beta,\gamma}^\delta$	0.0904	0.0872	0.0100	$\alpha = 2.39$, $\beta = 0.0001$, $\gamma = 1.4063$
x_α^δ	0.1732	0.1734	0.0019	0.0011
$x_{\gamma,C}^\delta$	0.2072	0.2070	0.0029	0.7850
$x_{\beta,B}^\delta$	0.1770	0.1766	0.0037	0.0146

Remark 5.2. In the considered experiments three-penalty regularization performs worse than the two-penalty one. It can be explained by the fact that $x_{\alpha,\beta,\gamma}^\delta$ involves the penalizing operator C that produces the poorest regularization effect when it is used alone in $x_{\gamma,C}^\delta$. The multipenalty scheme is still able to compensate this poor

TABLE 8

Numerical illustration for the function $\text{ilaplace}(100, 1)$. Statistical performance measures for the regularized approximations $x_{\alpha,\beta,\gamma}^\delta$, x_α^δ , $x_{\gamma,C}^\delta$, $x_{\beta,B}^\delta$, and 100 simulations of y_δ with 1% noise.

	Mean RE	Median RE	Standard deviation RE	Mean parameter
$x_{\alpha,\beta,\gamma}^\delta$	0.0680	0.0577	0.0320	$\alpha = 2.81$, $\beta = 0.0001$, $\gamma = 1.65$
x_α^δ	0.1298	0.1298	0.0007	0.0008
$x_{\gamma,C}^\delta$	0.3261	0.3086	0.1427	0.0005
$x_{\beta,B}^\delta$	0.0406	0.0404	0.0028	0.0583

regularization, but, in this case, this compensation appears at a lower performance level.

5.5. Four-parametric model function. In this subsection we demonstrate the adequacy of the four-parametric model function approximation using it as a tool for reconstructing the discrepancy domain. Recall that in view of Theorems 3.1 and 3.3 this domain $D(\delta)$ is of interest, because any point $(\alpha, \beta) \in D(\delta)$, where one of the parameters is sufficiently large, provides us with a solution $x_{\alpha,\beta}^\delta = u_{\alpha,\beta}^\delta + v_{\alpha,\beta}^\delta$, realizing an accuracy of optimal order.

In the previous subsection we have used the reconstruction of the discrepancy domain by a straightforward approach which consists in the direct calculation of the discrepancy $\|Ax_{\alpha_i,\beta_j}^\delta - y_\delta\|$ for all grid points

$$(\alpha, \beta) \in K = \left\{ (\alpha_i, \beta_j) : \alpha_i = \alpha_0 q^i \in Q_N^\alpha, \beta_j = \beta_0 p^j \in P_M^\beta, i, j = 1, 2, \dots, 40, \alpha_0 = \beta_0 = 0.0001, q = p = 1.3 \right\}.$$

Recall that we are interested in the parts of the domain where one of the parameters α or β is sufficiently large, i.e., greater than 1. Thus, we will reconstruct these parts of the domain separately by means of the model function approach. To this end, we distinguish two cases:

1. if $\alpha > 1$, then for each $\alpha_i \in Q_N^\alpha$ and $\alpha_i > 1$ the parameter $\beta_{k+1} = \beta_{k+1}(\alpha_i)$ is found by iterations (4.8) with an initialization $\alpha = \alpha_i$, $\beta_0 = 0.5$. The stopping criterion for the iteration (4.8) consists in checking that $\|Ax_{\alpha_i,\beta_{k+1}}^\delta - y_\delta\| \leq c\delta$;
2. if $\beta > 1$, then for each $\beta_j \in P_M^\beta$ and $\beta_j > 1$, $\alpha_{k+1}(\beta_j)$ is found by (4.9) with an initial guess $\alpha_0 = 0.5$ and $\beta = \beta_j$. We terminate the iteration (4.9) when $\|Ax_{\alpha_{k+1},\beta_j}^\delta - y_\delta\| \leq c\delta$.

Then in accordance with Theorems 3.1 and 3.3 the domain below the points $(\alpha_i, \beta_{k+1}(\alpha_i))$ for all $\alpha_i \geq 1$ and $(\alpha_{k+1}(\beta_j), \beta_j)$ with $\beta_j \geq 1$ can be seen as an approximate reconstruction of the discrepancy domain.

Figure 7 displays the reconstruction of the discrepancy domain for the problem *shaw(100)* with 1% noise in data. Each dot corresponds to the indices (i, j) of the parameters α_i and β_j , respectively, such that $(\alpha_i, \beta_j) \in D(\delta)$; crosses indicate the indices of the parameters in which we are interested, namely, $\alpha_i > 1$, $35 < i \leq 40$ or $\beta_j > 1$, $35 < j \leq 40$. The red lines represent the approximation of the boundary of the domains $D(\delta) \cap \{\alpha > 1\}$, $D(\delta) \cap \{\beta > 1\}$ found by the model function approach. As we can see the domain reconstructed by means of the model function almost coincides with the one found by the direct calculation of the discrepancy for all grid points.

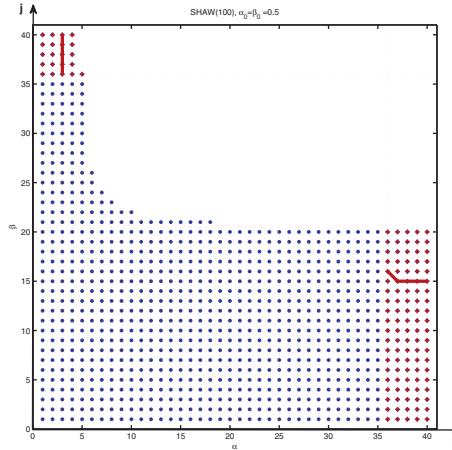

FIG. 7. Discrepancy domain and its reconstruction by means of the model function for the function $\text{shaw}(100)$.
